

Sami's three-minute opening

Use this guide for rehearsal. Project the separate presentation PDF.

Your route through the deck

180 seconds

Frame	Purpose	Time window	PDF pages
1	Introduce yourself and Bob	0:00–0:18	1–2
2	Show the next-day feed	0:18–0:40	3–5
3	Explain the recommendation job	0:40–0:59	6–8
4	Explicit and implicit feedback	0:59–1:24	9–11
5	Read the user–item matrix	1:24–1:48	12–14
6	Build a content profile	1:48–2:16	15–17
7	Compare directions and rank	2:16–2:44	18–21
8	Ask the handoff question	2:44–3:00	22–23

How to deliver it

Use the next two pages as a rehearsal script. The time windows include clicks and pauses. Practise once with a timer, then adjust to your natural pace.

- Start on page 1. Use single-page, full-screen mode. There are 22 advances to reach the final page.
- Look at the audience for “Coincidence?” Point at Bob’s matrix row and the two angles. Explain the picture; do not read every formula symbol.
- Ask the final question yourself, pause, then turn to your teammate. It is a handoff, not a Q/A invitation.
- If over time, omit “A familiar theme keeps appearing” and frame 6’s numerical-profile sentence. Retain the feedback distinction and handoff.

What the rubric rewards

30 marks

Criterion	Marks	Where this deck supports it
Technical slide quality	8	TikZ figures, native mathematics, staged Beamer overlays.
General slide quality	5	Limited copy, consistent palette, strong contrast and spacing.
Slide contents	5	Feedback, matrix, content features, similarity and limitation.
Presentation	10	Bob’s story, timed delivery, purposeful gestures and handoff.
WoW factor	2	Editorial photography, restrained visual identity and reveals.

Let Bob introduce the problem.

1 / Your next favorite.

0:00–0:18

Hello everyone, I'm Sami. Today we're exploring recommendation algorithms. I'll skip the formal definition and let our friend Bob help us. On Saturday morning, Bob wakes up, grabs his phone, and watches a funny YouTube video.

Click cue: Page 1: greet the audience. Advance to page 2 on "our friend Bob."

[Sources] Bob is fictional; generated photograph. The opening and Saturday story follow Sami's brief.

2 / Sunday looks familiar.

0:18–0:40

The next morning, he sees more movie bloopers, sitcom clips, and stand-up comedy. A familiar theme keeps appearing. This cannot be just a coincidence. Something is happening behind the screen. What happened here is what we call a recommendation system.

Click cue: Page 3: "The next morning." Page 4: "sitcom clips." Page 5: "coincidence."

[Sources] [1] supports watch history as a signal. This is an illustrative story, not a guaranteed next-day outcome. Generated video imagery; original TikZ feed mockup.

3 / A ranked guess.

0:40–0:59

It observes Bob's behavior, builds a model of his preferences, scores candidate videos, and ranks them. The result is an informed guess about what he might enjoy next.

Click cue: Page 6: "observes." Page 7: "builds a model." Page 8: "ranks them."

[Sources] [2]; simplified teaching pipeline. Original TikZ diagram and illustrative ranking bars.

4 / Bob tells us in two ways.

0:59–1:24

Bob gives two kinds of feedback. Explicit feedback is what he says: a rating, a like, or a dislike. Implicit feedback is what he does: how long he watches, whether he replays, or whether he skips. These actions are clues, not proof that he liked something.

Click cue: Page 9: explicit feedback. Page 10: "Implicit feedback." Page 11: "clues, not proof."

[Sources] [3]; original TikZ stars and watch-progress graphic.

Checkpoint at 1:24: Bob's story is complete, and the audience knows where feedback comes from. You have 96 seconds left for the matrix, content-based explanation and handoff.

Turn the story into a model.

5 / A few ratings. Many unknowns.

1:24–1:48

We can organize ratings into a user–item matrix. Rows are people; columns are videos. Bob gave bloopers five stars. Most entries are unknown. Unknown does not mean disliked. We want to score a video Bob has never rated.

Click cue: Page 12: point from Bob to the 5. Page 13: reveal the full matrix. Page 14: emphasize the highlighted question mark.

[Sources] [3]; original toy data, with five observed ratings and seven unknown entries.

6 / Describe videos. Learn Bob’s taste.

1:48–2:16

One approach is content-based filtering. Describe videos using features such as comedy and action. Combine those features with Bob’s feedback to build his taste profile. In this small example, his profile is three for comedy and one for action. Then compare new videos with that profile.

Click cue: Page 15: name the approach. Page 16: reveal item features. Page 17: reveal Bob’s profile.

[Sources] [4]; original illustrative feature vector and TikZ diagram, generated video image. The vector is a teaching assumption, not an estimate fitted to the preceding table.

7 / The closer direction wins.

2:16–2:44

Here, each arrow represents a feature vector. The sitcom points almost in Bob’s direction; the action trailer points further away. Cosine similarity compares their directions. We get zero point nine five for the sitcom and zero point five four for the trailer, so the sitcom ranks first.

Click cue: Page 18: point to Bob. Page 19: show A. Page 20: show B. Page 21: reveal the formula and final recommendation.

[Sources] [4,5]; exact original calculation shown on page 4 of this guide, original TikZ geometry, generated thumbnails. “Sitcom 2” is a new candidate, different from the rated “Sitcom 1.”

8 / Can Bob discover something different?

2:44–3:00

But a friend might ask: what if people with Bob’s taste love a video with completely different tags? That leads to collaborative filtering, which my teammate will explain next.

Click cue: Page 22: ask the question and pause briefly. Page 23: say “collaborative filtering,” then turn to your teammate.

[Sources] [6] for the limitation of matching existing interests; [3] for the collaborative handoff.

Scope boundary: You introduce the next method by name. Its mechanics, neighbors, matrix factorization and later topics belong to your teammates.

The numbers behind the picture.

The coordinates in frame 7 are **content-feature strengths**, not star ratings. For this illustration, let Bob's profile be $\mathbf{p} = (3, 1)$, the new sitcom be $\mathbf{a} = (4, 0)$, and the action trailer be $\mathbf{b} = (1, 4)$. Both axes have the same scale.

$$\text{sim}(\mathbf{p}, \mathbf{a}) = \frac{3 \cdot 4 + 1 \cdot 0}{\sqrt{3^2 + 1^2} \sqrt{4^2 + 0^2}} = \frac{12}{\sqrt{160}} \approx 0.9487,$$

$$\text{sim}(\mathbf{p}, \mathbf{b}) = \frac{3 \cdot 1 + 1 \cdot 4}{\sqrt{3^2 + 1^2} \sqrt{1^2 + 4^2}} = \frac{7}{\sqrt{170}} \approx 0.5369.$$

The angle to A is about 18.4° ; to B, about 57.5° . A has the smaller angle and the higher cosine score. These scores are similarities, not probabilities of enjoyment. Cosine compares direction, normalizing away vector length. It is undefined for a zero vector; a real system must provide a fallback when a usable profile is missing.

Keep three distinctions clear. Ratings record feedback about a particular item. Features describe its content. A user profile summarizes the user's preferences in that feature space. A possible construction is a weighted average of positively received items' feature vectors; our $(3, 1)$ is simply chosen to make the example easy to see.
